

BUILD SETTINGS IN ARKIT

Like every time, we stress on the need for creating an Apple ID to store and share the app and any other projects properly.

Launch the Unity installer and make sure that iOS Build Support is selected in the installation options.

Select the Apple device and enable developer mode. Open Unity and create a new project by going to the asset store and find the Unity ARKit Plugin. Select that, then download and import it into your project.

Then click on the Edit menu and select Project Settings, then Editor and then Device(inspector). When the window opens, keep all options open by selecting Any iOS Device.

Click on the File menu on the top and click on Development Build in that window while checking ARKitScene. Go back to Build Settings and change some settings in the player inspector: select Player Settings and Other Settings (Inspector).

Enter any new Unique Bundle Identifier. Configure the camera and keep the environment open to check for changes. Click on the build and Run. When you do this the first time, Xcode will launch with a build failure which is expected. Then click on Buildtime, then select the folder Unity-iPhone and look for the Team button to get to a drop-down menu.

Click on the Apple device of your choice and under Deployment, head to the Product menu and click on Build. After that click run. You've just completed build ups in ARKit.

The sample code for a portal AR app is shown below with the same steps for ARKit:

```

•     public void UpdateMesh(ARPlaneAnchor arPlaneAnchor)
•     {
•         planeMesh.vertices = arPlaneAnchor.planeGeometry.vertices;
•         planeMesh.uv = arPlaneAnchor.planeGeometry.textureCoordinates;
•         planeMesh.triangles = arPlaneAnchor.planeGeometry.triangleIndices;
•
•
•         lineRenderer.positionCount = arPlaneAnchor.planeGeometry.boundaryVertexCount;
•         lineRenderer.SetPositions (arPlaneAnchor.

```
