

For every exercise in this issue, we have shown how to perform the same operation using both ARCore and ARKit, so at the end of the reading, you should be equally familiar with both platforms. Alternatively, you can choose to follow along the steps for only one of the platforms, if that is what interests you. Both these kits work by doing a few basic things. They can track plane surfaces, and can recognise images. The digital assets can then be used to pinned against the surfaces, or the images. As a creator, most of your work is telling the frameworks which assets to place, and how.

We don't stop there, it gets better. We even show you how to create shared or collaborative experiences, that allow your creations to be enjoyed by multiple people, simultaneously. What this means is that several devices can be synced to simultaneously act as a window into a shared augmented reality environment, from the viewpoint of each of those devices. If that piques your interest, what are you waiting for? Flip the page and dive right in!

As always, please do let us know your feedback on this issue by dropping in a mail to editor@digit.in. The same address can be used to request and particular topics you might want us to cover in the future.
