

the patient wouldn't. The tricky part came with analysing and confirming whether the statistical algorithm would hold well for patients in the future as the research took place when computing technology wasn't so advanced.

Thanks to the potentials of SAS, a predictor model could be created with a reduced error rate that helps understand what led to the disease. Want to know the best part? The data set, learning material and software coding are all available for free on the University's online module.

**Online Search Engines:** All content online is distributed among an endless multitude of websites. So how is it that you still get the exact thing as your search query in such a short time?

The answer lies with the software. Web search engines use a 'back-linking' algorithm that latches onto the meta-tags, URL indexes and NAP indexes of any website online (Fun Fact:- Google's supposed name was chosen to be BackRub). These backlinks work like tiny creepers that seep through the internet, searching for unique tags and deliver the content. A majority of these use advanced classification and treeing systems.

Web scraping softwares that store user data and cookies also work in a similar fashion albeit with a much different purpose. You can download the Twitter or Facebook API and watch how the software collects data about users in a matter of seconds. Think of it as a form of data farming.

**Netflix's Recommendation Engine:** Part of the reason behind why Netflix became a truly unique viewing experience is because the streaming service is designed to keep the viewer glued their sets as long as possible. The idea here is to recommend shows and movies that closely match the content of the user's history.

Netflix even released its user data to be used for seasonal competitions to understand how exactly they work. Models from all over the world pooled in to create a recommendation engine that works behind the shadows while viewers watch.

Many of such engines typically use augmented classification algorithms like C45, PART, Decision Stumps, Decision Tables and Multilayered Perceptrons.

## Jumping to advanced cases

Most data you've seen till now use simple machine learning tools and algorithms. But as technology marches on, so does the need for complex cases that can help the machine learn faster and continue without any sort of developer supervision.
