

Distributed machine learning model for handwritten digits recognition.

into distinctive features like the double-loop in an '8' and so on.

Building these features into a distinctive image, the modern neural networks can determine, often exceptionally accurately, the actual number that corresponds with the handwritten digit. Similarly, deep neural net-

works and overall deep learning can allow computers and software to train themselves over time to recognise complex features like faces or transcribe spoken words to written text.

How is it different from machine learning

Machine learning and deep learning are terms you've probably heard about constantly, with the strides they are making in technological development, unless you have been living under a rock. They are often thrown around in popular media as buzzwords that seem interchangeable in their usage. However, there is a significant difference in their processes and applications that have often baffled even novices in the field. Essentially, 'deep learning' is 'machine learning' since the former is a subset of the latter. It is the next evolution of machine learning. It is how machines will make the right decisions without a programmer or any other external force.

Why should you know the difference, you ask? Well, it notes the difference between Netflix recommending you what to watch next and Facebook

Deep learning is how Netflix figures out what you would like to watch next.
