

application. This is the ultimate evolutionary goal of developing ADASes - Advanced Driver Assistance Systems to the elusive point where there is no one in the driving seat to assist anymore. Several computing companies maintain long-term relationships with car manufacturers as they continue to work on embedded and real-time operating systems designed exactly to meet this end.

Today, automated vehicles are being produced by utilising deep learning and their functionalities are endless. Adaptive cruise control, automatic emergency braking, intelligent traffic sign recognition, lane keeping assistance, traffic jam assistance are some advanced applications of ADAS. These functionalities are based off sensing, the logic of which has been developed via deep learning. However, the driver is still responsible and can easily override the system laterally or longitudinally. There are four distinct steps

An automated car can perform numerous functions through sensing, mapping, processing and decisions.

or categories involved in ADAS which is accentuated by deep learning and machine learning. These include - sensing (image recognition), mapping (positioning), processing (fusion algorithms) and decisions (autonomous driving decisions).

In healthcare, deep learning can provides accurate analysis of diseases to doctors and help them treat them better and also make better medical decisions. It has found a firm footing in drug discovery, medical imaging (MRI, CT, ECG scans) and the treatment of Alzheimer's disease, which
