

Ask the average person about CNN and chances are they'll confuse it with a news channel. Convolutional neural networks or CNNs are a driving force for a new age of machine learners that is enabling both researchers and industries to rethink their approach in interpreting the world around them.

Convolutional neural networks were created as an off shot extension of more advanced training algorithms that are used in high scale data-intensive tasks such as identification, classification and ultimately automation.

WHAT ARE CONVOLUTIONAL NEURAL NETWORKS

CNNs are powerful deep learning algorithms that perform tasks for both output generation and output classification. They are used primarily in image processing, artificial intelligence, video recognition, recommendation engines and natural language program softwares.

Like the traditional neural network with nodes and junctions, a CNN has nodes that represent the bits and pieces of the content. Since single images can't be fed to the nodes at a single point, images and similar content are broken down to low-resolution pieces. Similar to the human brain where the world's imagery is broken, transferred, reassembled and interpreted, CNNs are styled after the frontal cortex which is associated with interpreting stimuli in humans.

A CNN works much similar to a multilayer perceptron that has been designed for reduced processing requirements. All the layers of a CNN have
