

When choosing for the right software, keep in mind that a majority of them are common in the fact that they all support AI models created in a front-end tool such as MXNet, PyTorch, CNTK or TensorFlow.

These are usually compiled for an optimised execution pathway with a heterogeneous back-end DL that connects the software platforms with the hardware platforms. Intel's smart new AI driven setup that has graphics processing units, central processing units, field programmable gate arrays all under a single platform. Intel's best capabilities as a compiling and package resource are well seen by the nGraph's ability to abstract core computational graphical structures of a neural network in a variety of runtime environments.

And that's pretty much the tip of the iceberg. The Intel® Math Kernel Library that we touched upon earlier has some amazing and highly-optimised performance primitives for deep learning applications.

Intel Deep Learning Tools

This again means that users won't have to spend time wasting away by changing codes in the setup if they're using MKL. All that's needed is to relink the application to use Intel® MKL, and you too can bring the fullest potential of the newer Intel processors to any standard deep learning project.

The Intel® Math Kernel Library for Deep Neural Networks likewise is an open source performance library, available for free, that serves as a great tool for deep learning applications with greater emphasis on network training and neural networks.

This library provides optimised deep neural network primitives that rapidly integrate into any deep learning framework. The community too
