

```

pets.config \
• - trained_checkpoint_prefix training/model.ckpt-XX\
• - output_directory "graphfoldername"

```

And with that, you should be ready to move on to the more complex coding part of object detection. But wait, don't just close the entire window and start looking for cases to work on. Use the following code to check on the status of the trained data and then see whether the system is updating it on a regular basis.

```

• Object-Detection
• -data/
• --test_labels.csv
• --train_labels.csv
• -images/
• --test/
• ---testingimages.jpg
• --train/
• ---testingimages.jpg
• ---...yourimages.jpg
• -training
• -xml_to_csv.py

```

If you want to work on the Object Detection API straight from the online module, you can prep it up by the following command:-

```

• cd $HOME
• git clone https://github.com/GoogleCloudPlatform/tensorflow-object-detection-example
• cp -a tensorflow-object-detection-example/object_detection_app /opt/
• cp /opt/object_detection_app/object-detection.service /etc/systemd/system/
• systemctl daemon-reload
• /opt/object_detection_app/decorator.py
• systemctl enable object-detection
• systemctl start object-detection
• systemctl status object-detection
• systemctl stop object-detection
• ln -sf /opt/graph_def/[MODEL NAME]/frozen_inference_graph.pb /opt/graph_def/frozen_inference_graph.pb
• systemctl start object-detection

```

The last two lines are a nifty way of creating an online form on the API
