

1. Software emulator likes Android SDK and NDK.
2. The primary build system for TensorFlow-Bazel that can be downloaded from the main repository.(\$ bazel build //tensorflow/contrib/android:android_tensorflow_inference_java)
3. If you're running the object detection API on an android system, then have a compiler for c/c++ in eclipse.
4. As discussed from the introductory chapters, it's important to have cython installed on the system using the \$ pip install --no-use-wheel --no-cache-dir Cython h5py code.
5. Have opencv installed for simpler conversion of images to the required file formats? This can be done using the command cv2 \$ conda install -c conda-forge opencv.
6. Apart from the rest, have numpy, matplotlib and scipy installed on the system.
7. To incorporate the optimized system specifications from Intel which can be a huge life saver if running a large project, simply open up the prompt tab from the Python console and enter:
 - export PATH=/PATH/gcc/bin:\$PATH
 - export LD_LIBRARY_PATH=/PATH/gcc/lib64:\$LD_LIBRARY_PATH.
 - bazel build --config=mkl --copt="-DEIGEN_USE_VML" -c opt //tensorflow/tools/pip_package:
 - build_pip_package
 - bazel-bin/tensorflow/tools/pip_package/build_pip_package ~/path_to_save_wheel
 - pip install --upgrade --user ~/path_to_save_wheel /wheel_name.whl

Use the following code to download and import all necessary packages before executions:

```

• import numpy as np
• import os
• Import six.moves.urllib as urllib
• import sys
• import tarfile
• import tensorflow as tf
• import zipfile
• from collections import defaultdict
• from io import StringIO

```
