

human eye regardless of whether they are being viewed outdoors under the sun or indoors under a bulb. The same cannot be said of digital cameras. They will capture differences in the object basis the lighting of the surroundings. This would eventually mean your photos are left having a colour cast - an overall colored tint (usually blue or orange). This colour cast makes photos seem unnatural and wholly unappealing.

To combat this, cameras allow you to correct these colour casts by telling them the temperature of your scene. To do so, you need to use the white balance setting and tell your camera the lighting your scene has. Once the camera has this information, it will use an appropriate colour temperature.

Lens Distortion

Have you noticed photographs where certain aspects of the subject or the subject itself look disproportional in comparison to real life? Or you notice that buildings look like they're tipping? This is usually the result of a phenomenon known as lens distortion. Regardless of how much money you have invested into your lens, they all come with a little distortion. But guess what? Most of it can be corrected in post processing. And a little bit of distortion may actually be desirable in some photographs.

Lens distortion, simply put, is when your lens produces curved lines instead of producing straight lines. The two most common kinds of distortion are barrel and pincushion.

Your eye is drawn towards the centre of the image where the building looks disproportionately larger
