

An extreme example of lens distortion

In the following section, we are going to see how to perform different photo editing tasks. For this purpose, we will be using GIMP software. Let's begin:

Lens Distortion Correction

Usually found in photos that have a continuous texture that spans across the image, the photos often tend to show a fisheye effect where the appearance of the edges of the image seems to be curved inward or outward. This often makes editing or normal colour corrections difficult leading to even more distortions in the image. Therefore fisheye distortion or lens distortion is one of the first tasks in any image editing sequence. Like most image editing software, GIMP also provides a quick and easy filter to remove lens distortions from images. To remove the distortion, follow the below guidelines:

- Go to Filters > Distorts > Lens Distortion
- This will open up a dialog with numerous parameters ready for modification.
- The preview image provides an excellent preview of how the image will look like after you have made your necessary changes. So you can start moving the main slider in the negative or positive direction based on the effect you need in your target image.
- You can also zoom in to preview how it renders in the lowest resolutions.
