

Noise Removal

Digital cameras often have some kind of noise in their captures. Therefore, removing them is important to get clear images where the objects can be clearly visible. One of the most efficient ways to get rid of noise is the Gaussian blur.

The basic idea behind selective Gaussian blur is to blur the areas in the photo with contrast below a certain threshold. You can also find numerous noise removal plugins for GIMP that use significantly better algorithms to find and remove the unnecessary grains from the image. The best way to modify any image is to at first begin with a copy of the image. Then follow these steps to remove any noise through the Gaussian blur. Instead of applying Gaussian filters to the whole image, the selective Gaussian blur applies only to selected portions of an image. This allows you to select a part of the image and then apply the filters to it. This is how you can do it:

- To select the grainy area, use the free select tool and drag on the intended portion
- Then from the menu, choose Filters > Blur > Selective Gaussian Blur.
- The Selective Gaussian blur dialog box will appear where you can modify the maximum delta and blur radius in the selected region of the image
- To remove grains in even smaller areas of the image, you can use the smudge tool and use its options box to configure the size of the smudge and remove the grainy sections in the image
