

- With a left-click, you can gently remove the noise by blurring the areas that have noise.

Improving Color

Regardless of the type of camera used, the images often turn out to be over-exposed to environmental lighting conditions. Thus the imperfections in lighting can be easily fixed through a slew of options readily available on GIMP. It provides a bunch of tools to correct colour in an image. There are both automated and manual tools for colour correction that can come handy depending on the type of image and the effect you want in the respective image. You can find these tools in the Color > Auto in the image menu. A brief description of each of the features are:

- **Normalize:** This is, in reality, a plugin used inside GIMP to act on underexposed images. It is used to adjust the whole image uniformly until the time the brightest section of the image is at the saturation limit. This automatically makes the darkest point in the image black. Because the algorithm depends on the lightest and darkest pixels in the image, any one pixel with a darker tone or lighter tone can have huge differences in the final output.
- **Equalize:** This is more often used to spread the colour of an image across the intensities available in the image. However it is only applicable for a
