

In this chapter, we will be taking a look at how concepts such as split toning, image brushing and blending affect the outcome of the image. Additionally, we will better understand how these tools work together to create layered images that have unique perspectives.

We will also be able to understand the concepts from a theoretical and practical point of view, as designers enhance their skill set to the next level. While composing a good shot is half the battle, a major effort needs to be undertaken when talking about editing on the PC.

Split Toning

Split Toning is a process where designers can add different colours to shadows and highlights. This makes the image pop-out and adds an emotional dynamic to the image. It can be used to replicate a certain feeling or reproduce a certain colour theme in the picture.

Before and after using Split Toning

This has made split toning one of the most powerful tools in the intermediate skill set. It's also a great way to make images stand out and capture our attention. A common way to accomplish this is to make the highlights yellow and shadows blue. Split toning is one of the best tools to use when initiating the editing process.

Understanding the histogram

The histogram is a graphical representation of the image in pixel formats. On the left side, we have the shadows, and the right side shows us the highlights. The middle section is a representation of the mid-tones. The vertical axis of the graph shows us the number of tones used for that aspect. It is affected by the tone curve, and designers can apply additional settings.
