

Histograms display pertinent information for three primary colours – RGB. Designers can understand how the different colour channels behave accordingly, with the grey overlap present. Histograms can also share information about other colours present as well.

Generally, a good histogram is one that renders most tones in the middle of the graph. This means that there are no dominant colours present in the picture or any lack of highlights or shadows. It's also a more balanced approach to editing and photography. If there are tones present at the edges of the graph, then there is an underexposure present in the picture.

The histogram shows designers an objective perspective of the correct amount of exposure and colour present in the image. It also helps compare against other images to show us the technical details behind a particular image. These details are perfect when understanding from a general overview.

Combined, the histogram shows us a plethora of possibilities as designers. Every modern PC editing software has a histogram present on the side, showcasing the range of colours present. A designer needs to understand the details present within the histogram to have a coherent overview of the image.

The histogram also shows advanced designers macro-level information about the image, which can then be analysed accordingly.

Spot correction

PC editing software like Lightroom and Photoshop have advanced tools to help remove blemishes, spots, acne or other unwanted elements.

Spot correction is a powerful tool and one of the go-to skills required when you're a professional designer. It's helpful in cleaning up portions of images that aren't going well with the overall picture. This process is also referred to as retouching a photo or making an image flawless.

One can use the clone stamp tool to emulate certain areas and copy over others. The Spot Removal tool in Lightroom gives you two options to clone or heal. Cloning allows you to get quick fixes done in the editing software of your choice. It's also a common tool available to all designers.

Healing is another tool available which automatically matches the texture, lighting, shading and colours of the sampled area. The selected area is then healed automatically, and the resulting image provides the desired outcome for that photo.
