

level view of the range mask applied. Whether you want a certain image brighter or duller, you can do so by applying range masks across the area.

Blending

Blending allows you to combine various layers or images into one smooth transition in the final composite. It also creates a smoother final product, after you're done with editing processes being applied to it. You can also use auto-blend tools to ensure that the process is done for you in advance.

You can opt for normal blending, which is also called threshold blending. It allows you to edit or paint each pixel to make it the resulting colour desired. It's a default mode when it comes to blending and allows you to make quick changes on the go.

Blending tool on Photoshop

You can also go for clear blending, which is when each pixel is edited and made to be transparent. This allows you to choose from a variety of shape tool features including paint bucket, brush or pencil.

You can also choose the darker colour between the blend and combine them to result in the darker final product. This can be done to quickly blend two distinct colours that aren't far apart in the colour scheme.

Multiply – is another blending tool that allows you to multiply the colour values of the blends and create a final solution. This is generally the middle-ground between disparate colours.
