

Designers can also use Lighten (opposite of darkening) or soft-lighten tools. Using this tool allows you to create the perfect middle ground between different colours. You can also use Hard-Mix which is when all colours conform to the RGB standard. This is a harsher approach to blending but is effective in micro-scaled projects. Blending tools can also be used to combine two colours within a single image.

Cloning

Cloning is a highly effective tool that allows you to create new image elements and hide unwanted ones. You can copy one area of an image onto another area, and it's a standard tool present in most major photo editing software packages.

The tool can be used in the retouching process, allowing designers to create cleaner outputs from generic images. The raw image can be error-free when cloning tools are used to copy and paste information onto the recipient.

The pixel of the covered area can be copied and pasted directly. This ensures that there are no spaces left or mismatched colours when leveraging the tool. Designers can press 'S' key to bring up the cloning stamp and click away at the desired area.

Since there is free range in the amount of cloning that can be done, designers must be careful about how they approach the tool. Cloning when brushing is the ideal solution can lead to errors in the final composition.

That's why designers must look at the picture holistically and then use the appropriate tool. Cloning can also be used to add new elements to the background of an image. This helps in creating more activity in the backdrop of the image while creating a complete final image.

Everything from trees to mountain ranges can be added using the clone tool, and the PC software is intelligent enough to ensure that the blending is done perfectly. Most modern software tools use AI to ensure that the blend is perfectly matched. You can then use other tools to smoothen out the image as per your requirement. **d**
