

You can essentially have a favourite brush that you use, and then send that brush via your mobile device to another designer. The following areas can be edited within the mobile editing ecosystem:

Colour - Adjusting the colour temperature of a specific area within the image. Designers can make certain areas warmer and colder.

Tint - The tint can also be changed as per the requirement of the image or the emotion being expressed.

Exposure - The image exposure can be quickly set using the exposure feature within the mobile application.

Highlights & shadows - The highlights and shadows can also be changed to find the right balance in the lighting of the image.

Contrast, saturation and clarity - Designers can have all the controls in their hands as they edit the contrast and saturation of the image. They can find quick themes and edit the image to reflect their overall vision on their mobile devices.

Sharpness and noise - Designers can also change the level of sharpness that the image has, along with the background if any. The histogram can reflect more information when it comes to advanced editing.

Filters (radial, gradual, etc.)

Contrary to popular belief, mobile users can use filters as well. They can adapt gradual and radial filters via premier apps and edit their images on the go. It's one of the newer tools to be added to the mobile arsenal and designers can get acquainted with it to maximise their potential.

Users can drag from the top and create a filtered effect on the images that they're using. The functionality, although limited, is similar to that what you can get on the PC. However, the quality of the image is the same. Added to that, users can also use the tool to create quick iterations of design ideas and rough sketches.

Mobile editing gives users the flexibility to approach filters the same way they would on PC. They can darken the sky, add various colours to an image or blend in multiple formats. It's an exceptionally helpful tool when trying to create unique experiences from regular images.

If there is an end vision in sight, and a brand requirement that must be fulfilled, then quicker iteration helps in saving time. This can allow for rapid prototyping when it comes to both radial and gradual filtering.

After selecting the area of choice, users can tap on highlights, exposure, saturation and a host of common features that they can find on the PC. This
