

angle to give it a more novel look. Having a landscape being reflected on the water below is an ideal format for practising reflection techniques. Other use cases can include abstract artistic renditions and nature-driven phenomena.

After inverting the reflected image, you should then start experimenting with the opacity and depth of the inverted image. You can do so by directly changing the layer settings or masking certain areas while protecting others. This should be done when you're trying to perform macro level layers.

You can also start using the brush tool to get deeper into the micro details. This is done to enhance the quality of the reflection. If the reflection looks

Creating landscape reflection

uniform across various distances, it may look artificial. There is a chance of obstructions that may need to be worked around to create that perfect reflection look.

There are also cases where images have bad lighting, or the histogram reveals uneven tone use. This is when the reflection needs to absorb those qualities and show them on the image. This is when you can truly create a reflection that resembles the original concept. Otherwise, you may be creating an artificial looking reflection that stands out as bad artistry.

Designers must be careful about approaching the process of reflection with precision. Reviewing the opacity, depth and blending is critical when trying to get a perfect reflection. Additionally, it's essential to use the "lighten" blend mode when combining the image to the reflection. This is because the tool will allow you to smoothen out areas where the reflection is coming too strong to the picture.
