

Even when it comes to Full Blur, there are settings that you can leverage to change the intensity. You can even add a radial mask to apply the blur effects in localised areas.

It's important to work outwards from a specific element. If you're applying a blur to an object, then it's key to work around it. The blur should emerge organically from that object and not look like it's been added in post. As the camera captures even the minutest of details, it's important to make the overall image look as aesthetically pleasing as possible.

Reflection

Reflections make your image come alive and allow you to create magical moments out of stationary pictures. You need to ensure that the source image is of higher quality, as this is important to maintain throughout the process. Otherwise, the reflection comes out as dull and looks out of place.

You also need to focus on perspective and how you want the reflection to look in the end. It should look as natural and organic as possible, which is why complex editing tools are being used.

Another important concept that complex mobile editors must keep in mind is ray tracing. This is the idea that the ray should reflect the object in the most natural way possible. This means that the reflection can't possibly be a simple 90-degree flip. It needs to be blended and formatted as per the flow of the image. It's also important to have the right blend within the surface being used (road, water, etc.)

Additionally, it's important to understand what tools are available to the designer. Where there are free apps that give you a quick mock-up of the reflection, it's good to see a professional look. Using apps that offer reflection tools can help you see the finer picture in detail. You can find the image that you need to work it, duplicate it, and then flip the image as per the requirements. Blending the reflection to the recipient is an often-challenging process. It requires skill and a bit of work to produce. You can also brighten a certain point within the main image to bring out the colours and contrast when leveraging the reflection. This can also be done using pre-editing steps to make your ultimate reflection look cleaner.

After you've flipped and attached the reflection, you need to set the opacity at an optimum level. You need to do this so that you can create a more realistic reflection in the image. Otherwise, the reflection will come out as exactly the mirror opposite of the source. You need to do a bit of fine-tuning to the reflection to make it look organic and natural.
