

principles are applied here, with added elements that bring in the snow into the picture. It's important to review all the steps for yourself and experiment on your design and innovations.

Designers need to try out these processes for themselves to get a better idea about using them correctly. It's important to leverage the range of options available to get a better picture when composing a final image format.

Masking and colour correction

The overarching process starts by using a masking tool over certain areas where you want to work on. You can start with the grass and convert the image into a whiter hue. This can be done by applying a localised mask on an added layer. The grass can be converted into white snow by changing the hue and colour saturation of the grass elements.

Before and After Blending, Cloning, Masking & Colour Correction

Finer details can also be worked on, including the grass blades and the overall texture of the snow. Since snow has a softer feel to it, it's important to blend the grass after colour correction.

Adding elements to the sky

The next step is to focus on the sky and adding the snow elements to that. Not only that, but you will also have to change the colour of the atmosphere as well. It's not as simple as changing the colour in the image as that might affect the macro layer of the image. You need to deep dive into the individual parts that constitute the image.
