

The clouds will respond differently from the forest, which is why you need to have an individual approach to each element. Added to that, you need to focus on marking out individual layers on which you need to work. You can have individual layers for the sun, the sky and the grass underneath. This helps you edit the picture in its unique way.

No single edit affects the greater picture, and you get more control over the editing process. You can then start to recreate snow on the main image. This can be done by adding snow via the brush tool effects and stretching out the elements using the tool provided. This gives a more natural feathery touch to the snow, giving it more angles and emotion.

You can also copy paste the snow onto other parts of the sky and change them in dimension minutely. This should give you more perspective to work with and help you create unique snow elements in the image. Additionally, you can also add darker clouds in the skyline as well. These darker clouds can signify winter by greying out the tones and using the histogram.

Ultimately, the histogram will provide you with a more technical overview of the winter image.

Sun effects on darker tones

Including additional lighting is going to get you that natural winter sun look. This can be done using the light effects found in Adobe and leveraging the standard sun effect. The designer can be savvy about the process and recreate much of the winter sun in Photoshop. This is also helpful in the case where the image needs to be darkened (saturation, exposure, and hues) but needs a light source.

The areas above the mountains need to be brightly lit up to signify the sun behind the cloud. This also helps you create a more magical like feeling with your production. Even the house at the middle right of the image needs to get the right shadow to have a more natural look. Designers must have a keen eye for these things so that they can be better prepared.

The sun also has an interplay with each tree present. If the final image doesn't have strong enough shadows, then you need to add them in using Photoshop. This will help you get a more natural final image. The image will look more alive with the shadows accompanying the trees.

Depending on the light effect being used, the shadows may have to be edited accordingly. You can use masking tools to localise your edits and create shadows that have more depth. Shadows that are more intense have a
