

the information. You can start by analysing what categories you need to display, after which you can design your layout better.

You can then enter the right information into the appropriate categories. After that, you can highlight several rows or columns for special information, if needed, and work around those data points. If you're trying to display information visually, then the approach works here as well. You can also design more robust frameworks that capture all the information necessary.

A workbook is an extensive tool, especially when trying to run complex formulas. You need to have a basic understanding of what formulae to leverage while analysing the flow of data. Formulae can refine your data better and bring more perspective to the overall data set.

The spreadsheet structure is also important to analyse when working with larger data sets. It's best to create a framework first, and then entering the requisite information.

Common file formats in Excel

Acceptable formats in Excel

You can use different file types within Excel:

Excel Workbook (*.xlsx)

The .xlsx format is one of the more widely used extensions and file types for Excel spreadsheets. It's the default XML based file format and has been used for many years now. You can use this file type extensively and leverage it across various computing systems. It can't store any VBA or macro sheets that fall outside the default format.

Templates (*.xltx)

You can get the default file format for a template for both 2010 and

2019 versions. You can even use someone else's template and adapt it to your system. It's best to have a robust template that can be adapted across various systems. You can design unique templates that work well within different systems.
