

Adding a comment and a formula

You can perform the function in two ways. The primary way is to select a final cell in the sheet and type out the SUM formula for the data points. You can also add the “+” sign across a simpler data set to get quick results. The SUM formula is stated as “=SUM(D6:D7)” as an example. Following the PEMDAS rule, we can see how the information stored within the brackets is considered a priority.

You can then add the formula of SUM to it and get the final answer quickly. There’s another way that you can perform the function, and you can do so by clicking and dragging across a row or column. You can even do so on multiple rows and columns.

You can get a quick sum at the very bottom of the program, as an easier way to get the right answer. This is best when performing rough estimations or calculating a total across multiple rows as well.

You can also click on AUTOSUM for a particular row or column to get the right answer. The program will add up the information for you and give you the right final answer.

AVG: When to use and how

Finding the average is another important part of mastering Excel. You can perform the function by selecting the required row of information and typing in the appropriate formula in the cell. When it comes to finding the central data point within a range, or the average of a distribution, this function is the quickest and easiest to implement.

You can also set the range to extend outwards into the greater data set within your sheet. You can easily set an average number by selecting the
