

that feed this number into them. It is possible to train a Machine Learning algorithm based on the MIN or MAX.

Maximising impact with MAX

The MAX formula is written out clearly as “=Max(D1:D11)”. This reference formula can help find the largest number in a plethora of data points within a worksheet. It can also help in sorting out the data set better as you proceed from one data set to another.

The largest number can be the brightest candidate in a pool or the largest beneficiary in an NGO campaign. Finding the maximum number is useful in a wide variety of operations and situations. You can then perform complex iterations on that data by creating better algorithms. You can also design your Max to be from specific data sets as per the requirements.

The screenshot shows an Excel spreadsheet titled 'exceljet_max.xlsx'. The formula bar displays '=MAX(D4:D11)'. The worksheet contains a table with the following data:

	First	Last	Score
4	Sue	Brown	66
5	Sarah	Duncan	84
6	Justin	Gatt	69
7	Manfred	Hollis	77
8	Troy	Johnson	69
9	Aubrey	Sinclair	88
10	Gen	Tanaka	86
11	Renee	Zwrick	74

To the right of the table, there is a small summary table:

Max	88
Min	66

Adding a Min and Max

Labelling Max and Min is important so as not to have ambiguity in data presentation. Your findings should showcase the largest scope of work. You can then design complex models based on the Max and look at different applications of your number scale.

COUNT for better planning

COUNT and COUNTIF can be used to count specific mentions or the iterations of certain text or numbers. You can also use the COUNT function if you want to explore certain key areas within a data set. “=COUNT(Z1:Z5)”
