

Any sheet can have the capabilities of any other and not require manual editing across the board. This single-fit model is helpful when you have thousands of data points to scour through. Any single data point can contribute to a fresh insight that is obtained when you review it in another point.

Performing 3-D referencing in a sheet

3D referencing is used across industries, especially in areas where client data needs to be connected to vendor insights. This is also done extensively in fields where customer information needs to be stored in date sets and retrieved from them as well.

As information is passed from one sheet to another, it’s important to remember the right formulae to use. =SUM(2017:2018!\$A\$6) is one such 3D reference where information from two sheets are being pulled at the same time. This can be accomplished by entering the formula and then clicking the tab at the bottom. Then you can press Shift and add the second tab in the same formula. This gives you a comprehensive formula that captures information from both.

	A	B	C	D	E	F	G	H	I
1		Quarter 1	Quarter 2	Quarter 3	Quarter 4				
2	Coffee	\$8,752							
3	Tea								
4	Milk								
5									

North North (2) Mid South Company +

3D referencing across sheets

You can perform a 3D reference this way and ensure that the information is being preserved as is. You can also define new parameters along the way and create more unique formations. You can even create new lines of code that depend on multiple sheets being fed into the final algorithm. This is used in the particular case where customer research insights need to be analysed holistically.

Analysts often cluster the data across parameters and then study them individually using 3D reference sheets. This way, the data remains concurrent and fresh across all parameters. A reference of that is shared, with North and South data being referenced into the final sheet.
