

Ensuring that the actual value of the cell remains consistent is important. This is important to remember when it comes to having dynamic sheets or 3D referencing. These factors are important to keep in mind while deciding the layout of formatting or while implementing the actual process.

Cell formatting also covers protection and fill so that you can apply these filters to the final data. You can even colour code specific types of data so that you can visually get a better picture. You can design certain units to be filled in a certain way so that you can also get an overarching visual. Having that flexibility available allows users to become scale-focused and derive quicker information from that data.

The use of borders in formatting

You can click on the border icon to add a custom border to the cell. There are multiple options available here:

- **None** – This means that there is no border applied to the cell. It is the best way to show unimportant data or to hide lines away from that particular data point.
- **Outside** – An outside border can be applied when working with a range of data that needs to be highlighted. The border is a thick one that surrounds the resulting cells.
