

points to be analysed over time. You can get a sense of insight and delivery when you can gain perspective over what data is being transmitted and how it is being used in the enterprise.

A reference of COUNTIF would be –

=COUNTIF(B2:B55,"Awesome")

This formula can be used for machine learning analysis that checks for consumer sentiment with regards to the product.

SUMIF Conditional function

SUMIF allows you to create a new rule based on certain parameters. If the parameters are PASSED, then the resulting equation will add the numbers present. The data is then displayed as a total if and only if the condition is cleared. For data points in the worksheet that doesn't clear the test – the inputs are not taken into consideration.

You can use a variety of operators (>,<,<=,>=) and wildcards (*,?) for partial matching in the SUMIF conditional function. This gives you more flexibility when forming your conditions so that you can gauge the overall response of the code.

The syntax for SUMIF is generally represented as below –

=SUMIF (range, criteria, [sum_range])

This means that the numbers within the range are added up if the criteria are met. The range is then calculated, and the numbers are all added up. The function provides clarity with the adding function.

The screenshot shows an Excel spreadsheet titled 'exceljet_sumif.xlsx'. The formula bar at the top displays '=SUMIF(D4:D8,>100)'. The worksheet contains a table of sales data and a summary table.

Rep	State	Sales
Jim	MN	\$100
Sarah	CA	\$125
Jane	GA	\$200
Steve	CA	\$50
Joan	WA	\$150

Examples	Total	Formula
Total > \$100	\$475	=SUMIF(D4:D8,>100)
Total by Jim	\$100	=SUMIF(B4:B8,"Jim",D4:D8)
Total in CA	\$175	=SUMIF(C4:C8,"ca",D4:D8)
