

You can choose to create different filters and layers within the document to show that a certain criterion is being met. A lot of work can be avoided and simplified with the SUMIF conditional function to give you instant results within the same workspace.

You can also analyse various additions and means based on the SUMIF function. If there are different geographies or splits into the data, then you can perform complex functions based on the core answer generated by SUMIF.

IFERROR Conditional function

A reference IFERROR function is shown below –

=IFERROR (T1/L1, “Please enter the right value”)

This function will show the written message when there is an error detected in the formula. Instead of displaying a standard error message or a VALUE based message, it's better to have a more professional approach.

Most coders have these messages designed into the main spreadsheet by default, as they want to create a unique Excel experience. If you understand the parameters of using IFERROR, then you can create remarkable experiences with the function. You can design the right message when the condition is met or show the value if there is no error found. It's a robust tool that can be used at any skill level.

This formula helps refine your work process, and showcases a sense of professionalism and style. The general syntax is presented below –

=IFERROR (value, value_if_error)

This means that the value is critical to understand. If the right value has been added to the core function, then the result will be as per the rules stated. A lot of beginners make the mistake of having the function say a message when there is no error found, not understanding that the function is only designed to work with error messages.

The importance of Lookup functions

Lookup functions work perfectly when you're trying to design a search and recover feature in the Excel domain. It also works when you're creating a table that can have interactivity built-in. When analysts prepare their projections or focus on robust features to be built-in, they can ask for a value look-up for a certain parameter. This helps in keeping the core formulae proprietary or hidden.

You can use the Lookup functions to provide clearer insight into what data is being used where. It's a great way to address the evolving nature of
