

data and perform quality correlation to find metrics. The lookup function is then the perfect option to use when trying to find the correlating answers.

Lookups are easy to execute and are a standard advanced formula. This means that there is no need for add-ons or complex coding using VBA. You can search for the Lookup function on the cell and then type the value needed. You can then specify the array within the worksheet to get an answer.

You can also use the reference syntax listed below –

=LOOKUP (lookup_value, lookup_vector, [result_vector])

This can be used as a one-column or one-row lookup as well when you select the appropriate parameters. It's important to get the syntax right as you need to define the numbers as they are. If there is a wrong number entered, the output is simply the closest neighbour above the reference point. This gives accurate and quick results, and is also a simple tool for customers to use when working with a financial planner or healthcare specialist.

Using HLOOKUP in Excel

Another specific advanced formula is the HLOOKUP function in Excel. You can use the advanced solution to lookup certain values in a row. The H stands for Horizontal, and the subsequent rules are applicable under the LOOKUP family of formulae. It's best used in the case of billing and inventory management, especially in cases where there is a larger data set present.

Since sifting through the data points individually is tough, you can use the right HLOOKUP to ensure that you're getting the right correlation.
