

=INDEX (array, row_num, [col_num], [area_num])

Here we can see how the array is a critical component of the INDEX function. It doesn't work similar to LOOKUP in this way. It doesn't need a specific array as to how LOOKUP works. You only need to include the final answer location, using the map's layout. Additionally, you're also looking out for the number of rows and columns when deriving the final answer.

Using the above syntax, you can find the specific INDEX value for that query term. You can use INDEX across a wide array of solution areas and find the best option for your query.

Using MATCH with INDEX

The MATCH function is also an important tool to use when looking at vast data sets. Essentially, the MATCH function is designed to help you locate the position of the keyword or query that you're looking for. You can use this for multiple keywords as well so that you can design a more robust architecture of data.

A reference formula is shared below, where users can find the location of fruits in an array. This is helpful to find the top performers of the day or the locations of specific instances of data. You can use approximate, exact matching, and wildcards (* ?) for partial matches as well using MATCH.

If the data is well managed and there is uniformity in presentation, then you can uncover deep insights by reviewing where certain data points lie. You can then source the core reasons behind it by looking up different
