

values. You can also do so by working backwards from the data location. There are significant advantages to having the right MATCH function.

Here is the right syntax to use when working with MATCH –
`=MATCH (lookup_value, lookup_array, [match_type])`

INDEX & MATCH are often used together to bring out the inner meaning behind data sets. You can locate specific data points and find their position in the list by using both formulae. This is advanced level processing that you're performing by using the latest technologies available.

INDEX and INDEXOF

INDEXOF helps you find the first occurrence of the specified term or keyword. The value that INDEXOF presents shows you what location the actual term is in.

For large datasets with multiple participants, there is a need to locate the first instance of a certain word, number of key-item. This could be the first sale of the day, the first mention of a customer, or the first agent that was assigned to a case. There are multiple advantages to using INDEXOF, and it should be used in conjunction with INDEX. You can also use MATCH to find the exact information about where it was positioned.

While INDEXOF is critical, having the right design in your formulae is pertinent here. Design framework issues may arise wherein you have too much information flowing in from INDEX and MATCH. That's why INDEXOF comes into play and provides only the information necessary at that time. You don't need to keep looking up the location of the instance. You can do so rapidly by using INDEXOF. Additionally, it's important to have a clear approach when using INDEXOF. It only serves a primary purpose and can't be used for scale-driven operations.

Text Manipulation and Excel

Excel is one of the best tools when it comes to extracting meaningful text-based insights from data. You can enter a host of data sets into the spreadsheet and have the capabilities to parse individual strings. You can also design the algorithm to join two strings or look at extracting the left or right characters.

Text manipulation also involves extracting key phrases from within a cell. You can use a variety of functions within the text family. You can calculate the first three or four letters, count out the number of characters in a word or even remove spaces that are unwanted. This helps in getting meaningful
