

data ready across the board. If you have thousands of data points in the spreadsheet, then it makes sense to have text manipulation on-board. You can also focus on particular keywords that revolve around certain labels.

Additionally, using text manipulation saves time as well. You can focus on data handling and insight derivation when you're done with assessing the data. You can also start working on the data itself within the text. If you want to source the contact details but have their names jumbled into the cells, then using text manipulation tools is a good idea. You can do so by creating the appropriate formula that extracts the information from the text-laden cell. Text manipulation is a key factor when it comes to determining the right approach to cell mapping and insight derivation.

Example of text manipulation before and after

Concatenating in Excel

Concatenating is the art of combining two rows or cells or columns into one coherent message. You can combine different pieces of information into one or define a new row based on the addition of the original parts.

You can use the “&” symbol to concatenate two distinct arrays within the worksheet. You may want to combine two data sets into one to transport the information quickly.

You can also use concatenation before using Lookups to engage in additional information gathering. You can add text to numbers and vice versa using the concatenation tool.

Here is the reference syntax that you need to type out for concatenation.
CONCATENATE(text1, [text2], ...)

This is simple enough to add to the sheet and illustrate using a core text. You can even create complex sentences that act as information insights when combined with different information pieces. Financial analysts may perform this function when working with disconnected data points. Rich text insights can be added to the original text.
