

Ideally, it's best to have a uniform approach when it comes to formatting and design. Having an eye for design can enhance your career in the Excel domain.

Adding labels to charts

Probably the most important area of visual representation is needed to be done via labelling. With the help of proper labelling, you can design more impactful charts. It also helps in distinguishing between the many charts available in a particular worksheet.

This is also a great tool to use when you have multiple data sets being used. Here's how you can create an effective label in your chart –

1. Go to the chart tools layout tab available on the dashboard.
2. You can then click on the data labels button in the label's group. This should be visually represented as well.
3. You can find a menu of data label placement options available to you. Some of them are the centre, inside-end, and inside-base. These options are designed to prepare all labels universally.
4. You can finalise on the appropriate label and finish the setup.

The default name for the label is generally the series name. You should change this to represent the correct information better. This can also be used effectively when you have different layers of information to display.

Using Excel, you can design more robust algorithms and create extensive charts within the domain. Additionally, you can have your chart be the focal point of your presentation with the right labels attached to the information shared. Remaining consistent with your labelling practices is ideal.
