

to ensure that you don't need to open the default Excel to perform complex functions. You can do everything from inside the VBA itself.

The most important aspect right now is how to create a macro inside of VBA. This is the first step in learning more about VBA and performing more complex processes. The steps are simple.

1. You need to open the developer tab inside of Excel. It's located on the top and is available when you enable it inside of customising the ribbon.
2. After you open customise the ribbon, you can select the developer option in the drop-down menu. This should enable the developer tab to become visible.
3. You can then go to Developer and click on Insert Command Button. This is an important step as it pertains to the initiation of the macro.
4. You can now assign a macro to that button which is now placed inside of Excel. Excel has now become interactive with different elements attached to it. You can right click on the button and go to "view code". This should help you design your first macro.
5. You can view the entire project within the dashboard and enter the appropriate code inside.

Alternatively, you can even open Visual Basic directly by using Alt+F11. The editor pops open, and you can now experiment with different macros available in the dashboard. Don't forget to save your work so that you can use it again.

Variables in VBA – Understanding them better

When you're working with VBA, you're going to hear a lot about variables. It's important to have a clear understanding as to what they are and what they can do. Variables are key input parameters that can be used in the system. Essentially, variables are a named memory location used to hold any value. The value can then be changed as per the execution. You can create different resources using these variables and create algorithms based on them.

When naming a variable, you need to follow the compliance rules that apply to nomenclature. You also need to assign a realistic variable so that the code can run smoothly. When it comes to VBA, there is much to be said about how it is used. However, at the code level, the variable is any memory that is holding on to information. You can declare a variable as follows –

```
Dim <<variable_name>> As <<variable_type>>
```
