

You need to start by enabling the core developer option in Excel. If you've followed our previously outlined steps, then you may have it already open. Let's start with a basic Hi world program that can be written in the following way.

Every VBA program that you write will have the boundaries listed as below

```
Sub name()  
. End Sub
```

Sub is how the program starts and ends itself.

You need to create a new button on the sheet, using the steps listed previously. You can rename the macro to btnHiWorld_Click and click on the new button. A code window should pop open next.

You want to enter the following information now –

```
name = InputBox("Enter name")  
MsgBox "Hi " + name
```

Essentially, you've created a new variable and have created the box with the entry field. You can enter your information inside the box, and the return message should say Hi + name. You can click on the box and enter your name to test it out. You can also click on the button to type different names, and the result should be consistent. This level of functionality is simple to perform on VBA but difficult to do when only using Excel.

Professional advantage of using VBA

By using VBA extensively, you've displayed your skillset to the employment bodies that are looking for quality talent. You've also managed to discover new traits within the ecosystem of Excel. Added to that you're able to produce now more complex algorithms that can impact data systems and insights derived from core data.

You're also able to create complex applications that can run on proprietary data to uncover new insights. You can prepare better processes within the domain of Excel, to create a more compliant environment for all parties involved. Additionally, by having VBA in your skills arena, you're able to create a greater impact in the field of your choosing.
