

file attached to it. This is a common problem when it comes to badly coded VBA or tables. You can review the status of the file when it's offline.

Since it's a filetype issue, it's important to formulate the right compliances and measures to ensure that the file type remains consistent. If any single computer saves the file in another format, then the file could get lost in the ether. The data could be made difficult to retrieve as well.

The file type could also have made the file incompatible if someone had tried to change it using a brute force method. This is generally when someone renames the extension on the outside of the file (typically in a folder).

Check for Add-ons and third-parties

There are cases where a certain add-on or extension may have kicked off a chain reaction within the file. This may have caused the file to crash or the information to get locked. The data may have automatically gotten corrupted using a bad formula as well. That's why it takes significant skill to master VBA and understanding the impact of bad code.

You can also ask the owner of the file about third-party apps and extensions. If they're able to tell you all the extensions they've used, you can run a quick search for them online. You can then recover critical information from the community of Excel users and how they've recovered the data.
