

- **To go to camera view:** 'O' in the NumPad.
- **To toggle between orthographic/perspective view:** '5' in the NumPad.

A 3D scene has two views: orthographic, a form of parallel projection where a 3D image is mapped to a 2D plane, and perspective, which is viewing the object as the human eye sees it, objects closer in your view appear larger, perspective distortion comes into play.

The difference between these two views is seen below. The perspective view is the default view. To switch between views, we can also select View (from the header under the 3D View) and click on the desired view.

Perspective

Orthogonal

Now assuming you don't have a trackpad or a NumPad there are a couple of things you can do:

- Go to **File** menu in the Header section and then select **User Preferences...**
- Click on the **Input** tab
- Check the **Emulate 3 Button Mouse** and **Emulate NumPad** boxes
Emulate 3 button mouse substitutes the middle mouse button with Alt + Left Button

Emulate NumPad allows us to use the top row of numbers instead of the NumPad. (Originally the numbers in the top row are reserved for switching layers)

For zooming using the trackpad you can use **Ctrl + Alt + Drag**.

By default, Blender does not orbit around the selected object. It can be a pain when working on a large project with multiple objects. We can overcome this by :

- Go to **File** menu in the Header section and then select **User Preferences...**
- Click on the **Interface** tab
- Enable the **Rotate Around Selection** checkbox

There are many other options you can explore there like Auto Depth, Zoom to Mouse Position and Auto Perspective.
