

shouldn't freeze the other. This would ensure that the user has every aspect of his work within reach, ideal for independent workers who need constant multitasking. Secondly, all the parallel windows should not overlap and form a convoluted workspace; they should instead follow a subdivision-based structure so that users can use several windows simultaneously. Of course, the system should use shortcuts and hotkeys that are not specific to the software but universally accepted for easier handling. Simple tools such as copy, paste, select should have keyboard shortcuts that are generally used so that there is uniformity in the work. All of this leads to an interface much more tied together and ergonomically designed for people who want fast, efficient work to be done, leading to work that is not context based or dependent on other apps.

Over the years as different types of software have popped up most of them have come to follow these general guidelines, but Blender has acted as a precursor to most them by setting the trend with its friendly interface and adapted and became simpler to understand all the while, making it much less daunting to a stranger.

Selecting and transforming objects

Perhaps the most basic tool in the extensive Blender library, nonetheless important, the first tool we learn about is the selection of objects in the interface, and transformation of said object by moving it, rotating it, or scaling it.

We can do this in several ways, the simplest of which is by the mouse. Simply hovering over the object and right clicking selects the object. To double check you can see that there is an orange border around it, showing selection. This object is now active.

In case you need to, you can select multiple objects by holding down your shift key and right-clicking the object. Unlike most software, Blender uses right click for select instead of the left click for easier selection, as every other function is done by left click, so selection with a left click as well makes it slightly harder to select the correct objects when there are many. To change this for users who prefer the left click option for select, one can simply go to **file> user preferences> input> select with** and change the default from right to left.

The next way of selection is Toggle Select All. By using the hotkey A, you can select all the objects in the interface, but beware, since this is toggle select, if even one object is already selected the toggle select automatically deselects all objects. It is a simple method to select several objects, and one
