

can then use the shift-select method to deselect objects not needed. Next, we can select objects using Box Select. It works as one would imagine, by pressing the hotkey B, a crosshair comes up on the screen. Using left click drag, one can select all the objects that come under the box drawn by the crosshair. Middle click drag (using the scroll button) deselects the selection in the same way. By right click, one can exit the tool in the interface.

We then have the Circle Select, operated by hotkey C. This tool works more like a paintbrush, when the circle comes up we can change the size of the brush by scrolling up or down to make it bigger or smaller respectively, and we can then paint the screen, selecting the objects we want. One can start and stop this multiple times, and all the objects don't necessarily have to be selected in one go.

Box Select and Circle Select

Transforming an object

Once we select an object, we can change its position in several ways as well. When an object is selected a manipulator is present, we can left-click drag along a particular line to move an object along the X, Y or Z axis freely.

If the object is to be moved freely, we simply left click inside the small, white bordered circle at the middle of the manipulator and drag it around in the viewport.

To scale or rotate an image there are specific manipulators at the bottom of the screen, which can be used to do so.

Transforming an image using hotkeys is easier and more efficient once the user is familiar with it. To move an image, we can use the hotkey G (for grab), and the selection immediately turns its border from orange to white, indicating that it is in active mode to be transformed. Without even pressing down on the mouse we can move the object around in the viewport. Once satisfied with the location, we can left click to confirm, or right-click to cancel the operation. If we need to go back and undo the movement, we can press
