

Alt-G to make the object go back to its original place. To move the object along a particular axis, after pressing G, we can press X, Y or Z to restrict its movement to those coordinates only.

Using hotkeys R and S for rotation and scaling, similar actions can be performed along an axis or freely. In the rotation, using the hotkey R twice ensures that the rotation happens freely and not just in the viewport angles.

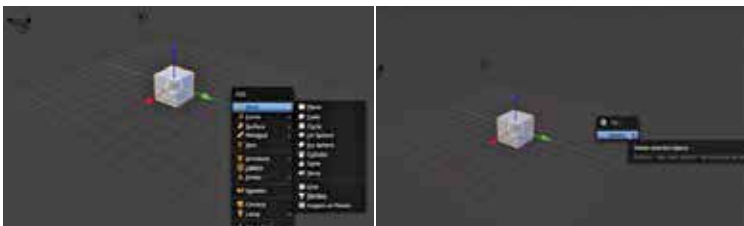

Moving an object along a particular axis

## Adding and deleting objects

In Blender, we can add primitives (objects such as cubes, spheres, toruses, cones etc.). To do so by using the mouse, we can go to the left of the screen and click on the + that is present, which opens up a plethora of tools. (This can also be done by simply pressing hotkey T). We then go to create and can choose from several options of the shape we want. The object is automatically created where the 3D cursor is, which can be moved by left clicking where we want it to be, this cursor acts as birth or 'spawn' point for our object.

Similarly, we can simply press Shift-A, and a menu automatically pops up with options for what kind of objects we want to add. These objects can now be transformed as per wish. To delete an unwanted object, we can select it and press X (or delete). A confirmation menu comes up, and to delete we can either left-click to confirm, press D or Enter and the object is deleted.
