

Layers and Mesh Visibility

Hiding a mesh is quite easy in Blender, once selected, all one has to do is use hotkey H, and the object(s) selected are hidden. These layers are not editable anymore.

To unhide these layers we can use Alt-H, but this hotkey brings back all the hidden objects to visible mode. To be specific about what kind of objects we need to unhide, we can go to the panel on the top right of the screen where all objects are given in order. There is an eyeball icon present next to each mesh which indicates its visibility. To unhide a particular mesh, we simply have to go to the object we want and change its visibility.

Another way to do this is by using layers. On the bottom of the screen is the Layer Management UI (a grid of grey boxes). Here, a circle in the box indicates that the layer is non-empty. We can click on a box to change

Layer and object visibility

its visibility according to preference. To move an object from one layer to another, we can use the hotkey M, and then either click on the layer we want to shift it to or type in the layer number. Using the Layer Management UI makes work a lot cleaner and more efficient to do, and we can shift between several layers and change their visibility easily. We can also group several objects in one layer to make work faster.

Dark grey boxes indicate visible layers, while light grey indicates invisibly, we can use shift-click to make all non-empty layers visible. If a box has an orange circle, it means that the active object is in that particular layer.

Pressing a number on the number row makes that particular layer come up on the screen. Pressing shift-1 (for example) changes the visibility of 1.
