

Loop cut and edge loop

Loop cuts cut your objects into parts using loops. By using hotkey Ctrl-R, you have an option to subdivide your object into two parts. The loops appear based on where your mouse cursor is, and you can left click to confirm which face of the object you want it on (and right click to cancel). Once the face is confirmed, you can slide the loop along the face of the object according to where you want it and left click to confirm (right click makes the loop fall in the centre as it cancels the sliding operation).

We can select edge loops and loop cuts using Alt+Right-click in edit mode and move them using the G tool (clicking G twice makes the loop normally slide along the face instead of moving freely).

Edge loops and loop cuts are useful when you want to extrude only a part of a face instead of the entire face, as we can extrude only the part we want.

Loop cut and bevels

Bevel

Bevelling allows the user to keep the realism in 3D modelling because no edge is truly completely sharp. By adding a bevel, the object looks much more realistic (like how a dice is a bevel on the edges and not a true cube).

To bevel, we can go into the modifiers tab and use the drop-down menu to go to Bevel. Here, we can adjust the width, a smaller width gives a sharper width and vice versa, and we can also change the number of segments, which determines the smoothness of the vertice. Bevel with smoothening (done in the tools tab) gives a very realistic result of a chiselled object. Alternately, we can also Bevel in edit mode by pressing Ctrl-B, and then dragging the cursor to fix the amount of bevel, then left click to confirm (or right-click to cancel).

With increasing support for a wide variety of tools, Blender continues to be a mainstay in the 3D industry. At the time of writing, Blender 2.80 is currently in beta and the community waits with bated breath for the modifications and cuts that will make it to a new and improved Blender. **d**
