

Texturing is the process of defining how a 3D model would look in the final output. Pieces of information such as colour, roughness, reflectivity, specularity, and even major details are added during texturing. It is the process of applying a 2D texture on a 3D model to add colour & detail information. The workflow and procedure may vary depending on the style of texturing. It can vary from just one texture to create an appealing character or combining multiple textures to create a more realistic output. Textures can help define a story for any 3D model. Textures can be anything from photographs to original designs. Texturing is an extremely important part of any production pipeline. A good texture can even hide flaws in the 3D model. There are many software packages used for creating textures. Some of the industry standard software packages are Adobe Photoshop, Allegorithmic Substance painter & MARI. Blender is an open-source 3D package which contains tools for texturing though it's not used widely by professionals.

Texturing is a highly creative process and is considered to be the first stage of giving life to a digital model. Different kinds of texture maps are used for this process depending on the desired result/workflow.

TEXTURE MAPS

Texture maps are 2D images which are wrapped around a 3D model based on the UV coordinates given during UV Unwrapping. UV Unwrapping is a process where a 3D model is cut and flattened to a 2D space. This map informs the computer which parts of the texture corresponds to which
