

6. Curvature Maps

Curvature maps are used to store information about the convexity or concavity of the mesh. These can be used to mask areas where the surface will get more wear, or Sub-surface scattering might occur.

7. Specular Maps

Specular maps hold information about how reflective the surface is. These maps usually simulate only reflections of the brightest light sources in a scene.

8. Gloss Maps

Gloss maps control the power of the specular highlights from real-time lights. A shader might also support control for the colour/intensity of the specular highlights.

9. Roughness Maps

Roughness maps are gloss maps in a Physical Based Rendering (PBR) system. It represents how smooth or rough a surface is.

10. Metallic Maps

Metallic maps control the metallicity of a surface. These are often considered to be an alternate to reflectivity in a PBR system. These are some of the most widely used maps in production. There are more maps such as Cavity map, Ambient Occlusion map, which add realism in a digital model.
