

3) 3D projection

3D projection is a technique which projects the texture through 3D space with height, width & depth, and without an exact polygon level mapping. This technique is mostly used in models which are not clearly visible in a scene. This technique is independent of the object.

4) Hand-painted textures

This workflow is used for a stylized look on a model. Blender supports texture painting within the software. This workflow only deals with the diffuse map. Variation in the diffuse map gives a stylized look to the model. Many software support texture is painting out of the box. UV unwrapping of the model is required for this technique to function properly.

5) PTex (Per face texturing)

PTex technique was developed by Walt Disney in 2008. The advantage of PTex is that no UV is required for texturing. The feature film Bolt was the first movie to utilise PTex workflow in their pipeline. This is the primary texturing workflow adopted in every Disney production. PTex applies the

texture to each face of the mesh removing the need for UV unwrapping the model. While PTex is extremely beneficial, it has not yet become the industry standard.

MATERIALS & SHADERS

Most beginners are confused while talking about materials and shaders. It is important to understand the difference between the two as a texture artist.

A material is a combination of attributes which describes how a surface of the given material should look like. It describes how a surface reacts to light. It will hold the basic properties like Base colour, Roughness, where different texture maps are plugged into. The available options for a material
