

Lighting

Adding lights to your imaginary world in Blender

Introduction

It is fascinating that all the objects you model and texture in Blender will be rendered black without lights in your scene. Of course, by default Blender has a Point Light present in your scene, so there will be some light in your scene, but it is still not enough to illuminate your scene properly. Without correct lighting, even well-modelled scenes will appear dark and gloomy. Sometimes, you can create amazing effects just using a careful set up of lights.

Let's first understand how light interacts with the colour, texture and material of the object to give the sensation we perceive through our eyes. Let's say we shine white light on a blue object. The visible colour of the object will depend on what colours of the white light it reflects (Remember that white light is composed of all visible colours). Represent the colour of the light ray and our blue coloured object with the following colour vectors:
