

in the space, and a cutoff angle around its direction where it is focused. The attenuation of spot light is slightly different from a point light, but we won't discuss it here.

Spot Lights are great when you want to focus your light in a conical volume. It is rarely used by developers but still one cannot neglect its importance.

Building a lighted scene

Now, enough theory about lighting, let's get our hands dirty with some actual work. Let's build a simple lighted scene in Blender and experiment with the little knowledge that we have. First model a simple scene containing a simple object. Here, we will use some sort of hollow cube with a subsurface modifier applied which will help us in understanding a different kind of light interactions.

To set up the following scenes, you must switch to Cycles Rendering Engine. You can do that by toggling the rendering engine displayed at the top of the view. For our first render, delete all existing lights, position the camera to the current view (you can do this using the hotkey Ctrl + Alt + Numpad0). Change the sampling (in the Render menu on the right pane) to around 100. Without any time wasted, render the scene.

Scene 1: Rendered only in Ambient Light in Cycles
