

Camera: This is the camera which will capture your render. Whatever the camera sees will be your final render. You can change its position and orientation just like any other object.

Object: It's the way to classify and group stuff together in blender. An object can contain one or more meshes (a connected group of vertices) in it, or it may be a light source or a camera to capture the final render.

The default Blender screen

To model an apple easily, delete the cube and add a UV Sphere mesh by pressing Shift + A to bring up the Add menu.

Add menu: This menu can be used for adding different kinds of objects at your 3D Cursor. You can add multiple objects through the Add menu.

Also, add a Cylinder object which you will use to make the apple's stem, and scale it to the appropriate size. You may add a plane for the sphere to rest on and scale it to some bigger size. Position everything in their approximate positions and get ready for modelling.

Modelling

The next crucial step is to model your bland and primitive meshes to something that resembles what you want your render to have. Modelling can be achieved in various ways. What we are going to look at here is the Edit Mode of Blender.

Till now, we were working in the Object Mode. Blender has several Modes to edit different aspects of our objects.
