

Add the Subdivision Surface modifier to the sphere in edit mode. You can now see the edges and vertices of the low-poly model, but the high poly model is also shown along with it. What's cooler is that if we grab one vertex and move it around, the high poly model is updated in real time! We can instantly see how changes in the low-poly model will affect the high poly model. This is a great point to shut your technical mindset and get your art juices flowing! This is the part where you grab some vertices, tinker with the positions and see if what you've made matches what you want to make. It is very helpful if you have some reference images open in another window, or in blender itself. There is no need to worry if you don't nail it the first time. After modelling the apple body, go back to Object Mode and hit 'Alt+H'. This will bring up the hidden objects. Select the cylinder this time and try to model it into a stem for the apple, by going into Edit Mode. Also, add Subdivision Surface Modifier to the stem too. Here are some tools and tips that may help you a lot:

Loop Cuts: While in Edit Mode, to add extra geometry to a model (the cylinder, for example), we can add loop cuts in the geometry by pressing 'Ctrl+R' and using the mouse to preview the cut. The number of cuts can be increased using the mouse wheel or just typing it in the Numpad.

Proportional Editing: Sometimes you want to drag one vertex but also want the rest of the geometry to warp accordingly, as though it were made of dough or clay. And sometimes you want to move some geometry of the model without affecting other vertices. You can easily toggle between these two effects by pressing 'O' on the keyboard. You can even change the radius of proportional editing using the mouse wheel. Moreover, different kinds of proportional editing can also be chosen from, using 'Shift+O' to cycle through the options.

Once satisfied with your result, go back to Object Mode, select the apple and the stem, and select Smooth under Shading in the Tools Tab on the left side of the screen. This will visually remove the hard edges on the polygons and make it look higher poly without actually increasing the polygon count.

Unwrapping

You have come so far and put so much effort into your model. It is time to save your Blender file now if you haven't already. Hit 'Ctrl+S' and navigate to the folder you want to save your file in. Then name your file and save it. It is recommended to save your file in a folder made specifi-
